(54) Title: FLEXIBLE STENT WITH ELEVATED SCAFFOLDING PROPERTIES

FIG. 5

(57) Abstract: The present invention concerns a stent including an essentially tubular body formed by a web structure that is configured to expand from a contracted delivery configuration to an expanded deployed configuration and that is composed of a plurality of longitudinally adjacent web rings (44, 46). Those web rings are formed by a plurality of web elements (32) disposed circumferentially around the longitudinal axis of the stent and adjoined one to the other with a junction bend (40). Each junction bend in a first web ring is coupled to another junction bend in a neighboring ring with a s-shaped connector (42), and the coupled junction bends are not longitudinally aligned but are instead laterally offset. The s-shaped connectors may have a different cross-sectional area or may be biodegradable.

WO 2008/142566 A1

FLEXIBLE STENT WITH ELEVATED SCAFFOLDING PROPERTIES

FIELD OF THE INVENTION

The present invention relates to a medical device. More particularly, the present
5 invention relates to a flexible stent that provides elevated scaffolding properties.

BACKGROUND OF THE INVENTION

Atherosclerosis, sometimes called the hardening or clogging of the arteries, is an
accumulation of cholesterol and fatty deposits, called plaque, on the inner walls of the
arteries. Atherosclerosis causes a partial or total blockage of the arteries and,
10 consequently, a reduced blood flow to the heart, legs, kidneys, or brain.

Traditionally, clogged arteries has been treated with surgical procedures that
involve the removal of the diseased arterial tract. Angioplastic procedures, during which
a stent is inserted in the diseased portion of the artery, have gained increased acceptance
during the last two decades because of the reduced complexity of the procedure, with a
15 consequent reduction in risk and discomfort to the patient.

Referring first to FIG. 1, a stent 10 is a small tubular element that typically has a
cylindrical structure 12 and that, once placed within a blocked vessel, acts as a scaffold to
keep the vessel open. Stent 10 may be implanted in a bodily vessel by disposing the stent
over a balloon tipped catheter and by subsequently inflating the balloon at a target
20 location. Alternatively, stent 10 may be caused to self-expand without the use of a
balloon by manufacturing stent 10 from a shape memory material and disposing stent 10
over a catheter in a contracted delivery configuration, successively allowing stent 10 to
self-expand at the target location.

One type of self-expanding stent is produced from a superelastic material and is
25 compressed inside a sheath into the contracted delivery configuration. When the stent is
released from the sheath, the flexible material causes the stent to spring back to its
original shape and size before compression. Another type of self-expanding stent is
produced from a thermo-elastic shape-memory material that is formed into a desired size
and shape and is then annealed at a temperature higher than a transition temperature.
30 After cooling the stent to a temperature below the transition temperature, the stent
becomes soft and can be reduced to a smaller size by compression, so that it can be
delivered to the target location, where the stent is warmed to a temperature above the
transition temperature, returning to the preprogrammed size and shape.

The following description relates to a balloon expandable stent, but it will be

appreciated that a self-expanding stent may be employed instead of the balloon expandable stent, when a clinician believes that self-expansion provides more desirable properties than balloon expansion, for example, due to stent recoil problems.

5 With reference to FIGS. 2A-2C, the placement of a stent 22 into an artery 14 having a buildup of plaque 16 is performed with a very thin tube called catheter 18. The distal end of catheter 18 contains a deflated balloon 20, onto which stent 22 is disposed in a contracted delivery configuration. Balloon tipped catheter 18 is inserted, using local anesthesia, into artery 14 with a needle puncture, typically in the groin, and is guided through the vascular system until its tip reaches the blocked tract of the artery. Balloon
10 20 is then inflated, deploying stent 22 until contact with the walls of artery 14 is achieved. The deployment of stent 22 causes plaque 16 to become compressed against the walls of artery 14 and also causes artery 14 to be widened and supported, improving blood flow 24.

Carotid arteries may experience a significant amount of plaque build-up. The
15 nature of the plaque varies considerably, but in a significant number of cases plaque may not only narrow the carotid arteries, but pieces of the plaque may break away and cause neurological impairment by blocking blood flow to specific areas of the brain. With reference to FIGS. 3A-3C, stenting of carotid artery 26 is complicated by the bifurcated disposition of carotid artery 26. As shown more particularly in FIG. 3A, carotid artery 26
20 travels from the heart to the head through the neck, supplying vital oxygen and glucose-rich blood to the parts of the brain where thinking, personality, speech, and sensory and motor functions reside. As shown in greater detail in FIGS. 3B-3C, plaque on carotid arteries 26 can be removed through a surgical procedure called carotid endarterectomy, which involves cutting an incision in the neck of the patient and in artery 26 at the site of
25 the carotid artery blockage. Artery 26 is isolated, and plaque 28 and diseased portions of artery 26 are surgically removed. Artery 26 is then sewn back together, improving blood flow to the brain and lessening the probability of a stroke.

An alternative procedure for treating blockage of the carotid arteries is carotid angioplasty, during which a carotid artery stent is inserted inside carotid artery 26 at the
30 site of blockage, providing a scaffolding of carotid artery 26 that keeps carotid artery 26 open and that reduces the risk of plaque becoming loose and reaching brain vessels. During carotid angioplasty, only local anesthesia is used as a tiny incision is made in the groin, and the patient remains alert and awake during the procedure, reducing recovery time.

The bifurcated anatomy and frequent movements of carotid artery 26 require that stents with a high degree of flexibility be employed for carotid angioplasty. Carotid stents in the prior art are formed as a metal mesh or, in general, as a web structure that provides some degree of flexibility. Each of the stent designs in the prior art, however, increases flexibility by increasing cells size in the mesh or web structure. Therefore, whenever stent flexibility is increased in stent in the prior art, scaffolding support is affected negatively.

An example of prior art stent is disclosed in U.S. Patent 5,104,404 to Wolff, which teaches an articulated stent in which stent segments, formed by diamond-shaped cells disposed in ring form, are connected one to the other at some but not all of the tips of the diamond-shaped cells. This arrangement provides for a stent with a high degree of longitudinal flexibility, but also for limited support to the arterial walls at the junctions areas between the different stent segments.

U.S. Patent 5,449,373 to Pinchasik also discloses a stent formed by a plurality of longitudinal stent segments that are connected one to the other by arched segments. This arrangement enables only a limited degree of longitudinal translation between the stent segments, reducing stent flexibility, and also causes one stent segment to rotate in relation to the neighboring segment when tensile or compressive forces are applied to the stent.

U.S. Patent No. 6,190,403 to Fischell discloses a stent having a plurality of stent segments that are disposed in longitudinal order. Each of the stent segments is formed by longitudinally-oriented cells disposed circumferentially and is joined to a neighboring stent segment by sinusoidal connectors connecting cell tips that are longitudinally aligned one with the other. The stent of the '403 patent provides an elevated degree of scaffolding to the arterial walls, but its structure allows only a limited degree of longitudinal flexibility, due to the limited extent of longitudinal translation between the stent segments that is possible when a compressive force is applied, because this translation is limited to the distance between adjacent stent segments.

U.S. Patent No. 7,029,493 to Majercak et al. discloses a stent structure having a plurality of wavy rings, joined one to the other by connecting neighboring crests of adjacent rings with curvilinear connectors. Because the ring crests are longitudinally aligned, the degree of motion of the different rings under compressive stress is necessarily limited to the distance between neighboring crests.

Therefore, it would be desirable to provide a stent that generates an elevated degree of scaffolding to a bodily vessel while remaining highly flexible.

It would also be desirable to provide a stent, in which adjacent stent segments can translate one with respect to the other for a distance greater than the distance existing between neighboring rings when the stent is at rest.

BRIEF SUMMARY OF THE INVENTION

5 A stent according to the present invention generates an elevated degree of support to a bodily vessel while retaining a highly flexible structure.

In one embodiment, a stent constructed according to the principles of the present invention includes an essentially tubular body formed by a closed cell web structure that is configured to expand from a contracted delivery configuration to an expanded deployed
10 configuration and that includes a plurality of longitudinally adjacent web rings. Each of the web rings, or crowns, is composed of a plurality of web elements disposed circumferentially around the longitudinal axis of the stent and adjoined sequentially one to the other with junction bends. Each junction bend in a first web ring is coupled to another junction bend in a neighboring web ring by a S-shaped connector, but the coupled
15 junction bends are not longitudinally aligned one to the other but instead are laterally offset.

Each of the crowns in a web ring is formed by a central member of essentially linear shape that is joined to terminal end members extending from the central element at an obtuse angle. The crowns of each web ring are nested one into the other in the
20 contracted delivery configuration of the stent. Preferably, the crowns of one web ring are oriented at 180 degrees (that is, have an inverted orientation) with respect to the crowns of a neighboring ring.

The S-shaped connector is formed by two arms that are joined by a curvilinear segment. Upon application of a bending force on the stent, for example, when the stent is
25 disposed along a tortuous path or when the patient moves, the two arms translate one in relation to the other by deforming the curvilinear segment, thereby providing flexibility to the stent. Because the junction bends coupled by the S-shaped connector are laterally offset, the junction bends are enabled to translate in response to a compressive force, but do not abut one against the other, but instead translate one sideways in relation to the
30 other, increasing the length of translation of the junction bends and the degree of flexibility of the stent.

With this configuration, the S-shaped connector effectively deforms to suit the movement of the crowns and provides greater flexibility to closed cell stent designs than stent designs in the prior art. The flexibility of the stent may be further tailored to

specific applications by providing S-shaped connectors with the same the cross sectional areas as the crowns, or by providing S-shaped connectors and crowns with different cross-sectional areas.

Methods of use of the stent according to the present invention are also provided.

5

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

The drawings constitute a part of this specification and include exemplary embodiments of the invention, which may be embodied in various forms. It is to be understood that in some instances various aspects of the invention may be shown exaggerated or enlarged to facilitate an understanding of the invention.

10

FIG. 1 is a perspective view of an essentially tubular body of a stent.

FIGS. 2A-2C are illustrations of a procedure for implanting a stent in a bodily vessel.

FIGS. 3A-3C are respectively illustrations of the anatomy of the carotid artery, of plaque buildup in a carotid artery, and of a carotid endarterectomy procedure.

15

FIG. 4 is a schematic view of the tubular body of one embodiment of a stent according to the present invention.

FIG. 5 is a detail plan view of the web structure of a stent according to one embodiment of the present invention.

FIG. 6 is an illustrative example of a tubular body in a flexed position.

20

FIG. 7 is a schematic plan view of a S-shaped connector connecting two neighboring junction bends in one embodiment of the present invention.

FIGS. 8A-8C are schematic plan views of a S-shaped connector in one embodiment of the present invention when at rest and in compressed and tensed positions.

DETAILED DESCRIPTION OF EMBODIMENTS OF THE INVENTION

25

The present invention relates to stent designs that provide an elevated degree of scaffolding to a bodily vessel while retaining a highly flexible structure. A preferred application of the present invention relates to closed cell stents, in particular, carotid stents, for which lesion scaffolding and the capability of conforming to tortuous anatomies are key design features.

30

Detailed descriptions of embodiments of the invention are provided herein. It is to be understood, however, that the present invention may be embodied in various forms. Therefore, the specific details disclosed herein are not to be interpreted as limiting, but rather as a representative basis for teaching one skilled in the art how to employ the present invention in virtually any detailed system, structure, or manner.

Referring to FIG. 4, a stent 26 constructed according to the principles of the present invention includes an essentially tubular body 28 expandable from a contracted delivery configuration to an expanded deployed configuration. While body 28 is depicted in FIG. 4 as cylindrical in shape, body 28 may be provided with other shapes, for example, with a frustoconical shape or with the shape of a hyperboloid.

Referring now to FIG. 5, body 28 is defined by a web structure 30, which includes a plurality of web elements, shaped as crowns 32 in the illustrated embodiment. In particular, each crown 32 includes a central member 34 having a first end member 36 and a second end member 38 extending respectively from the ends of central member 34. Central member 34, first end member 36 and second end member 38 are each essentially linear in shape, and, in the contracted delivery configuration of stent 26, central member 34 is disposed essentially perpendicular to the longitudinal axis of body 28, while first and second members 36 and 38 extend from central member 34 at obtuse angles. Preferably, first and second members 36 and 38 extend from central member 34 at the same angle, but in other embodiments, first and second members 36 and 38 may extend from central member 34 at different angles. In still other embodiments, one or more of central member 34 and first and second members 36 and 38 may be non-rectilinear and have a curved shape.

Crowns 32 are nested one into the other in the contracted delivery configuration and are sequentially adjoined at one end by a junction bend 40 having an essentially arcuate shape. Crowns 32 are disposed circumferentially about the longitudinal axis of body 28 to form web rings 44 and 46, which are joined one to the other by S-shaped connectors 42. As shown in FIG. 5, the crowns in one web ring may be disposed with an orientation that is opposite to the orientation of the crowns in a neighboring web ring. In particular, the crowns in web ring 44 are disposed with an orientation that is 180 degrees different from the orientation of the crowns in web ring 46.

Crowns 32 and S-shaped connectors 42 are typically manufactured from a biocompatible material, and, in one embodiment, may be made of a biodegradable material when it is expected that only temporary vessel support is required. In another embodiment, only S-shaped connectors 42 may be manufactured from a biodegradable material, so that the scaffolding provided by stent 26 may change over time and S-shaped connectors 42 will gradually dissolve in the fluid carried by the vessel (for example, blood), leaving web rings 44 and 46 intact and allowing web rings 44 and 46 to be disposed at specific angles as required by the patient's anatomy or by the movements of

the patient's body.

As also shown in FIG. 5, S-shaped connectors 42 do not adjoin two longitudinally aligned junction bends of neighboring web rings, for example, junction bends 48 and 50 from web rings 44 and 46. S-shaped connectors 42 adjoin instead two junction bends from neighboring web rings that are offset one in relation to the other, such as junction bends 48 and 52. This offset configuration is more advantageous than a configuration linking adjacent S-shaped connectors, because the configuration with S-shaped connectors 42 linking offset junction bends 48 and 52 provides greater flexibility to stent 26 than a configuration with S-shaped connectors 42 linking adjacent junction bends 48 and 50, as described in greater detail below. At the same time, vessel patency is maintained in the expanded deployed configuration by the elevated degree of scaffolding caused by disposing S-shaped connectors 42 to extend from each junction of a web ring, rather than from selected junctions only. Therefore, stent 26 is well suited for delivery and implantation both at sites that require elevated flexibility and elevated scaffolding, for example, in carotid arteries.

S-shaped connectors 42 may join adjacent junction bends 48 and 52 at different points within the junction bends. For example, in the embodiment shown in FIG. 5, S-shaped connector 42 adjoins the nearest points of junction bends 48 and 52 by extending from the lowest points of junction bend 48 to the highest point of junction bend 52, providing for an improved nesting of S-shaped connectors 42 within the structure of stent 26. It should be understood that in other embodiments S-shaped connectors may join junction bends 48 and 52 at different points of the junction bends.

FIG. 5 further shows that each of the junction bend is connected to an adjacent junction bend, causing stent 26 to be configured as a closed cell stent, different from open cell stents, in which only one every predetermined number of junction bends (for example, one every three) is connected to another junction bend. This design increase stent density and due to the relatively small cell sizes.

The mode of operation of stent 10 is illustrated further in FIGS. 4, 6, 7 and 8A-8C. Turning first to FIG. 4, it is known that, when body 28 of stent 26 is in a stationary, at rest condition, upper surface 66 and lower surface 68 of body 28 are subject neither to compressive or tensile forces. When elongated body 28 is bent, in the manner illustrated in FIG. 6, upper surface 66 becomes subject to a longitudinal compressive force C, while lower surface 68 becomes subject to a longitudinal tensile force T.

If body 28 is formed by open cells, the cells of compressed surface 66 will

decrease in size, while the cells of tensed surface 68 will expand. Such expansion of the cell openings is problematic in a carotid stents, because of the related reduction in arterial scaffolding.

Turning now to FIG. 7, crowns 54 and 56 become spread apart one in relation to the other during the expansion of stent 26 while remaining adjoined by junction bend 58. At the same time, the presence of S-shaped connector 60 causes crowns 54, 56 not to become longitudinally displaced from crowns 62, 64. Therefore, S-shaped connectors 60 cause stent 26 to maintain a substantially homogeneous scaffolding during expansion and prevents some cells from expanding to a greater extent than others, as may occur with open cell stents.

Turning now to FIGS. 8A-8C, the disposition of S-shaped connectors 70 also provides elevated flexibility to stent 26 while still maintaining the desired degree of scaffolding. In particular, FIG. 8A illustrates the at-rest configuration of an embodiment a S-shaped connector, identified by reference numeral 70, which connects junction bends 72 and 74 by extending from the lower end of junction bend 72 to the upper end of junction bend 74. The S-shape of connector 70 is composed of two essentially parallel arms 76 and 78 that are joined by a curvilinear segment 80. In other embodiments, S-shaped connector 70 may extend from different points of junction bends 76 and 78, and the S-shape may have a plurality of other configurations, for example, with curvilinear arms. The junction bends coupled by S-shaped connector 70 are offset by a distance L, allowing junction bends 72 and 74 to move laterally one in relation to the other, and, accordingly, allows the crowns connected to those junction bends also to move laterally one in relation to the other.

Turning now to FIG. 8B, upon application of a compressive force C, junction bends 72 and 74 and the crowns connected thereto become closer one to the other because curvilinear segment 80 deforms inwards, allowing the arms of S-shaped connector 70 to slide one in relation to the other. Therefore, junction bend 72 may translate past junction bend 74, to become situated proximally of junction bend 74, thereby increasing the ability of stent 26 to flex in comparison to stents in the prior art.

With further reference to FIG. 8C, when a tensile force T is applied, S-shaped connector 70 stretches by deforming curvilinear segment 80 outwards, thereby allowing junction bends 72 and 74 to move laterally one away from the other, so that stent 26 can bend to a significant degree. At the same time, junction bends 72 and 74 remain connected one to the other, thereby limiting the relative separation of junction bend 72

from junction bend 74 and retaining the scaffolding support of the walls of the vessel, within which stent 26 is implanted. Flexibility of the stent may be further tailored to desired results by varying the cross-sectional areas of the S-shaped connector 54 in relation to the neighboring crowns.

5 Stent 26 may include different features known in the art to provide certain beneficial properties. For example but not by way of limitation, stent 26 may be coated with a therapeutic coating that includes a bioactive agent, or may contain radiopaque markers, or may be coupled to a fabric that prevents the passage of emboli from the vessel wall into the blood stream.

10 Stent 26 may be disposed into a target vessel location, such a location within a carotid artery, by inserting a guide wire into the artery, and by successively translating a catheter along the guide wire that carries the stent in a contracted condition. When the stent has reached the target location, as may be determined by tracking radio-opaque markers embedded in the stent, a balloon disposed on the catheter and within the stent is
15 inflated, causing the stent to expand from the contracted condition to the deployed condition until contact with the vessel walls is achieved. Alternatively, if the stent is manufactured from a self-expanding material, after the target location has been reached, a sheath covering the stent is withdrawn, enabling the stent to self-expand until contact with the vessel walls is made and a support structure is created.

20 By providing a stent having a structure formed by web elements disposed in web rings and connected by S-shaped elements in the manner described herein, so to form a closed cell structure, an improved support is provided to the vessel walls in comparison with open cell stents, and a highly flexible structure is achieved that provides scaffolding support to the vessel walls even when the vessel is bent.

25 It should be noted that, while the invention has been described in connection with the above described embodiments, it is not intended to limit the scope of the invention to the particular forms set forth, but on the contrary, it is intended to cover such alternatives, modifications, and equivalents as may be included within the scope of the invention. Accordingly, the scope of the present invention fully encompasses other embodiments
30 that may become obvious to those skilled in the art and the scope of the present invention is limited only by the appended claims.

CLAIMS

What is claimed is:

1. A stent comprising:
a web structure defining an essentially tubular body expandable from a contracted delivery configuration to an expanded deployed configuration;
a plurality of longitudinally adjacent web rings defining the web structure; and
a plurality of sequentially adjoined web elements defining the web rings, the web elements being disposed substantially parallel to a longitudinal axis of the essentially tubular body when in the contracted delivery configuration, pairs of the web elements being sequentially adjoined at junction bends,
wherein each junction bend in a first web ring is connected to one junction bend in a neighboring web ring by a S-shaped connector, and
wherein two junction bends connected by the S-shaped connector are laterally offset one in relation to the other.
2. The stent of claim 1, wherein each of the web elements comprises a central member having a first and a second ends, wherein the central member is disposed essentially parallel to the longitudinal axis in the contracted delivery configuration, wherein the central member is connected at the first end to a first end member at a first obtuse angle, and wherein the central member is connected at the second end to a second end member at a second obtuse angle.
3. The stent of claim 2, wherein the first and the second obtuse angles are essentially equal.
4. The stent of claim 2, wherein the web elements of each web ring are nested one into the other in the contracted delivery configuration, and wherein the junction bends have an arcuate shape.
5. The stent of claim 2, wherein the web elements in the first web ring are oriented at approximately 180 degrees in relation to the web elements in the neighboring web ring.

6. The stent of claim 1, wherein the S-shaped connector comprises two essentially parallel segments, and wherein the two essentially parallel segments are connected one to the other by a curvilinear segment.

7. The stent of claim 6, wherein the two essentially parallel segments translate one in relation to the other upon application of a bending force on the essentially tubular body, thereby providing flexibility to the essentially tubular body.

8. The stent of claim 1, wherein the two junction bends comprise a first junction bend disposed distally from a second junction bend when the tubular body is in an at rest condition, and wherein the first junction bend translates proximally of the second junction bend without contacting the second junction bend upon application of an adequate compressive force on the tubular body.

9. The stent of claim 1, wherein the S-shaped connectors have a cross-sectional area different from the cross-sectional area of the web elements.

10. The stent of claim 1, wherein the web structure is manufactured from a biocompatible material.

11. The stent of claim 1, wherein at least the S-shaped connectors are manufactured from a biodegradable material.

12. The stent of claim 1, wherein the web structure is configured to self-expand from the contracted delivery configuration to the expanded deployed configuration.

13. The stent of claim 12, wherein the web structure is manufactured from a shape memory material.

14. The stent of claim 1, wherein the web structure is configured to expand from the contracted delivery configuration to the expanded deployed configuration by application of pressure to an interior surface of the essentially tubular body.

15. The stent of claim 1, wherein pressure is applied to the interior surface by expanding an inflatable balloon disposed within the essentially tubular body.

16. The stent of claim 1, further comprising a coating disposed on the web structure, the coating comprising a bioactive agent.

17. A method of stenting a bodily vessel comprising:

providing a stent having a web structure defining an essentially tubular body expandable from a contracted delivery configuration to an expanded deployed configuration, a plurality of longitudinally adjacent web rings defining the web structure, and a plurality of sequentially adjoined web elements defining the web rings, the web elements being disposed substantially parallel to a longitudinal axis of the essentially tubular body in the contracted delivery configuration, pairs of the web elements being sequentially adjoined at a junction bend, each junction bend in a first web ring being connected to one junction bend in a neighboring web ring by a S-shaped connector, two junction bends connected by the S-shaped connector being laterally offset one in relation to the other;

disposing the stent in the contracted delivery configuration in the bodily vessel; and causing the stent to expand from the contracted delivery configuration to the expanded deployed configuration, thereby providing a supporting structure to the bodily vessel.

18. The method of claim 17, wherein providing the stent comprises providing the S-shaped connector with two essentially parallel segments in the contracted delivery configuration that are connected one to the other by a curvilinear segment, and wherein the two essentially parallel segments translate one in relation to the other by application of a bending force on the essentially tubular body, thereby providing flexibility to the essentially tubular body.

19. The method of claim 17, further comprising the step of deploying the stent by applying pressure to an interior surface of the essentially tubular body.

20. The method of claim 17, wherein providing the stent comprises providing the web structure configured to self-expand from the contracted delivery configuration to the expanded deployed configuration.

* Special categories of cited documents:

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

- *T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- *X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- *Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- *&* document member of the same patent family

Date of the actual completion of the international search

29 September 2008

Date of mailing of the international search report

14/10/2008

Name and mailing address of the ISA/
European Patent Office, P.B. 5818 Patentlaan 2

INTERNATIONAL SEARCH REPORT

International application No.
PCT/IB2008/001851

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: 17-20
because they relate to subject matter not required to be searched by this Authority, namely:
Rule 39.1(iv) PCT - Method for treatment of the human or animal body by surgery
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers allsearchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of additional fees.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.
- ☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.
- ☐ No protest accompanied the payment of additional search fees.
